Emerging infectious diseases are a threat to biodiversity and fungal pathogens have caused rapid declines in amphibian populations around the globe. Gray et al. [1] identifies *Batrachochytrium salamandrivorans* (Bsal) as an emerging fungal pathogen that caused rapid die-offs of naïve salamanders in Europe and predicts North America will soon experience similar devastation if no policy actions are taken and the pathogen emerges. Epidemic dynamics of infectious diseases with multiple routes of transmission are complex. Mathematical models can be used to determine invasion potential and identify which transmission pathway is dominant, can ultimately help identify appropriate intervention strategies. We developed compartmental host-pathogen models to examine the transmission dynamics of an emerging fungal pathogen on an amphibian population. Multiple stages of infection are incorporated into the model, allowing disease-induced mortality and zoospore shedding rates to increase as the disease progresses. Parameter sensitivity analysis, calculations of the basic reproductive number, and numerical simulations shed insight into pathogen dynamics.
