

A Note on Bicyclic Antiautomorphisms of Mendelsohn Triple Systems

Brittian Qualls*, Neil P. Carnes, McNeese State University

A cyclic triple, (a, b, c) , is defined to be the set $\{(a, b), (b, c), (c, a)\}$ of ordered pairs. A Mendelsohn triple system of order v , $\text{MTS}(v)$, is a pair (M, β) , where M is a set of v points and β is a collection of cyclic triples of pairwise distinct points of M such that any ordered pair of distinct points of M is contained in precisely one cyclic triple of β . An antiautomorphism of a Mendelsohn triple system, (M, β) , is a permutation of M which maps β to β^{-1} , where $\beta^{-1} = \{(c, b, a) | (a, b, c) \in \beta\}$. Necessary conditions for the existence of a Mendelsohn triple system of order v admitting an antiautomorphism consisting of two cycles of lengths M and N , where $N > 2M$ have been shown, and in some cases, sufficiency has been shown. We show sufficiency for some additional cases.

Keywords: antiautomorphism, bicyclic, Mendelsohn triple system
